Based on the paper “Intracluster light is a biased tracer of the dark matter distribution in clusters” (Butler+25).

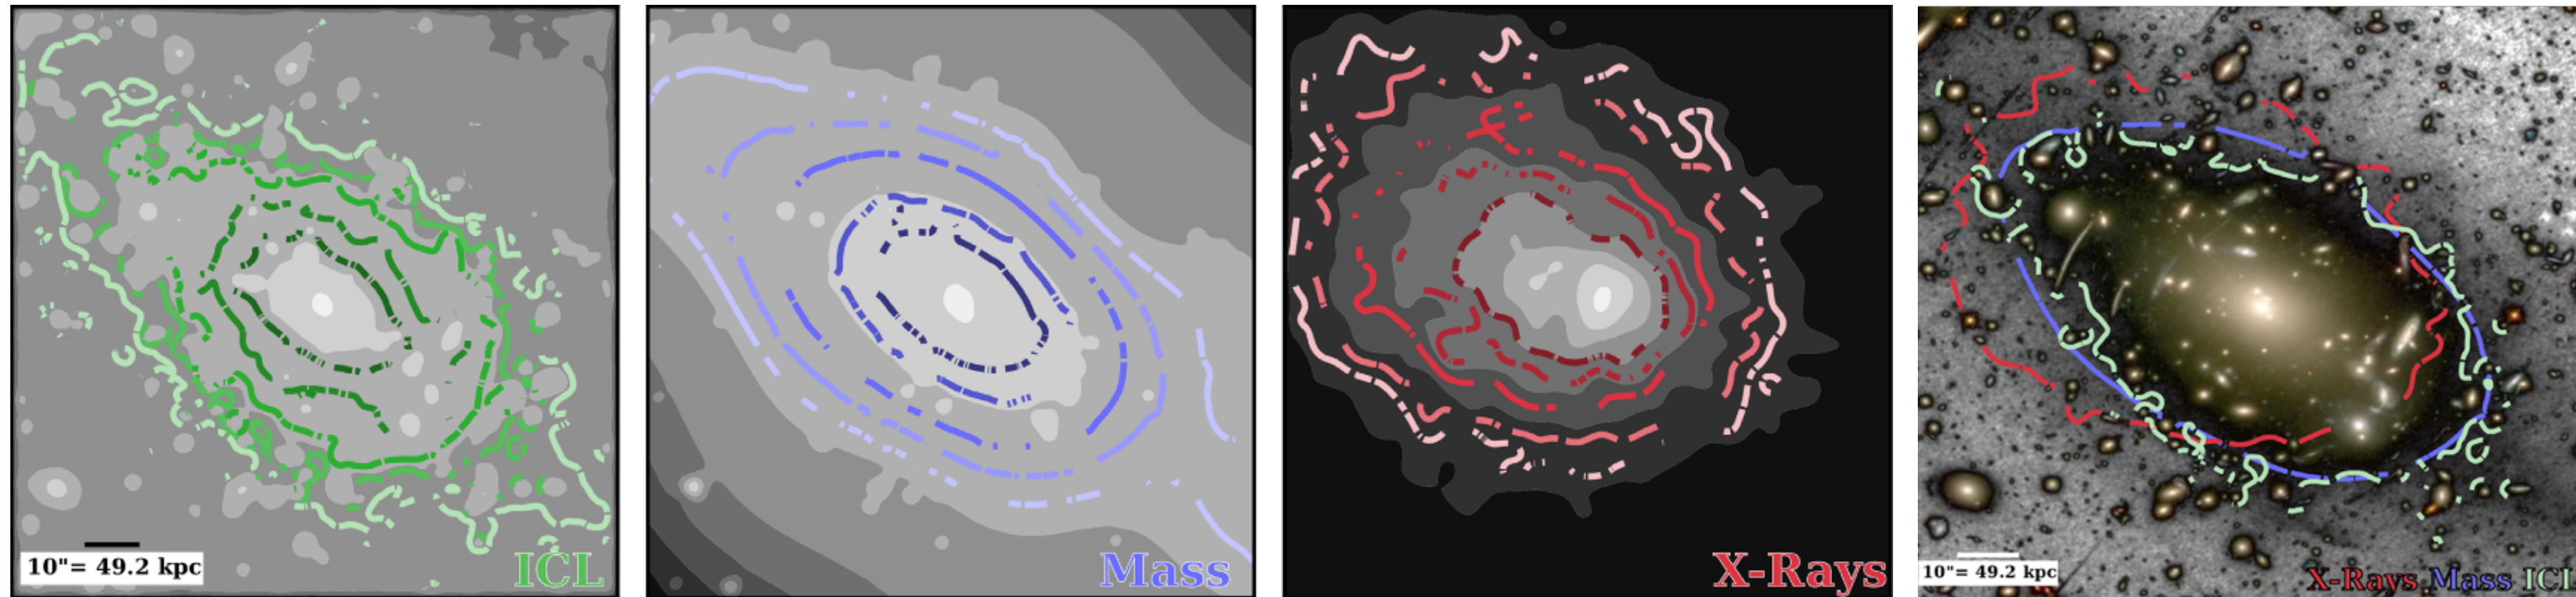

Intracuster Light: A Dark Matter Tracer?

- Intracuster stars and dark matter (DM) are both collisionless, so dynamics governed by cluster potential.
- Orbital properties must be compared to understand how these components are related.

Montes & Trujillo 2019

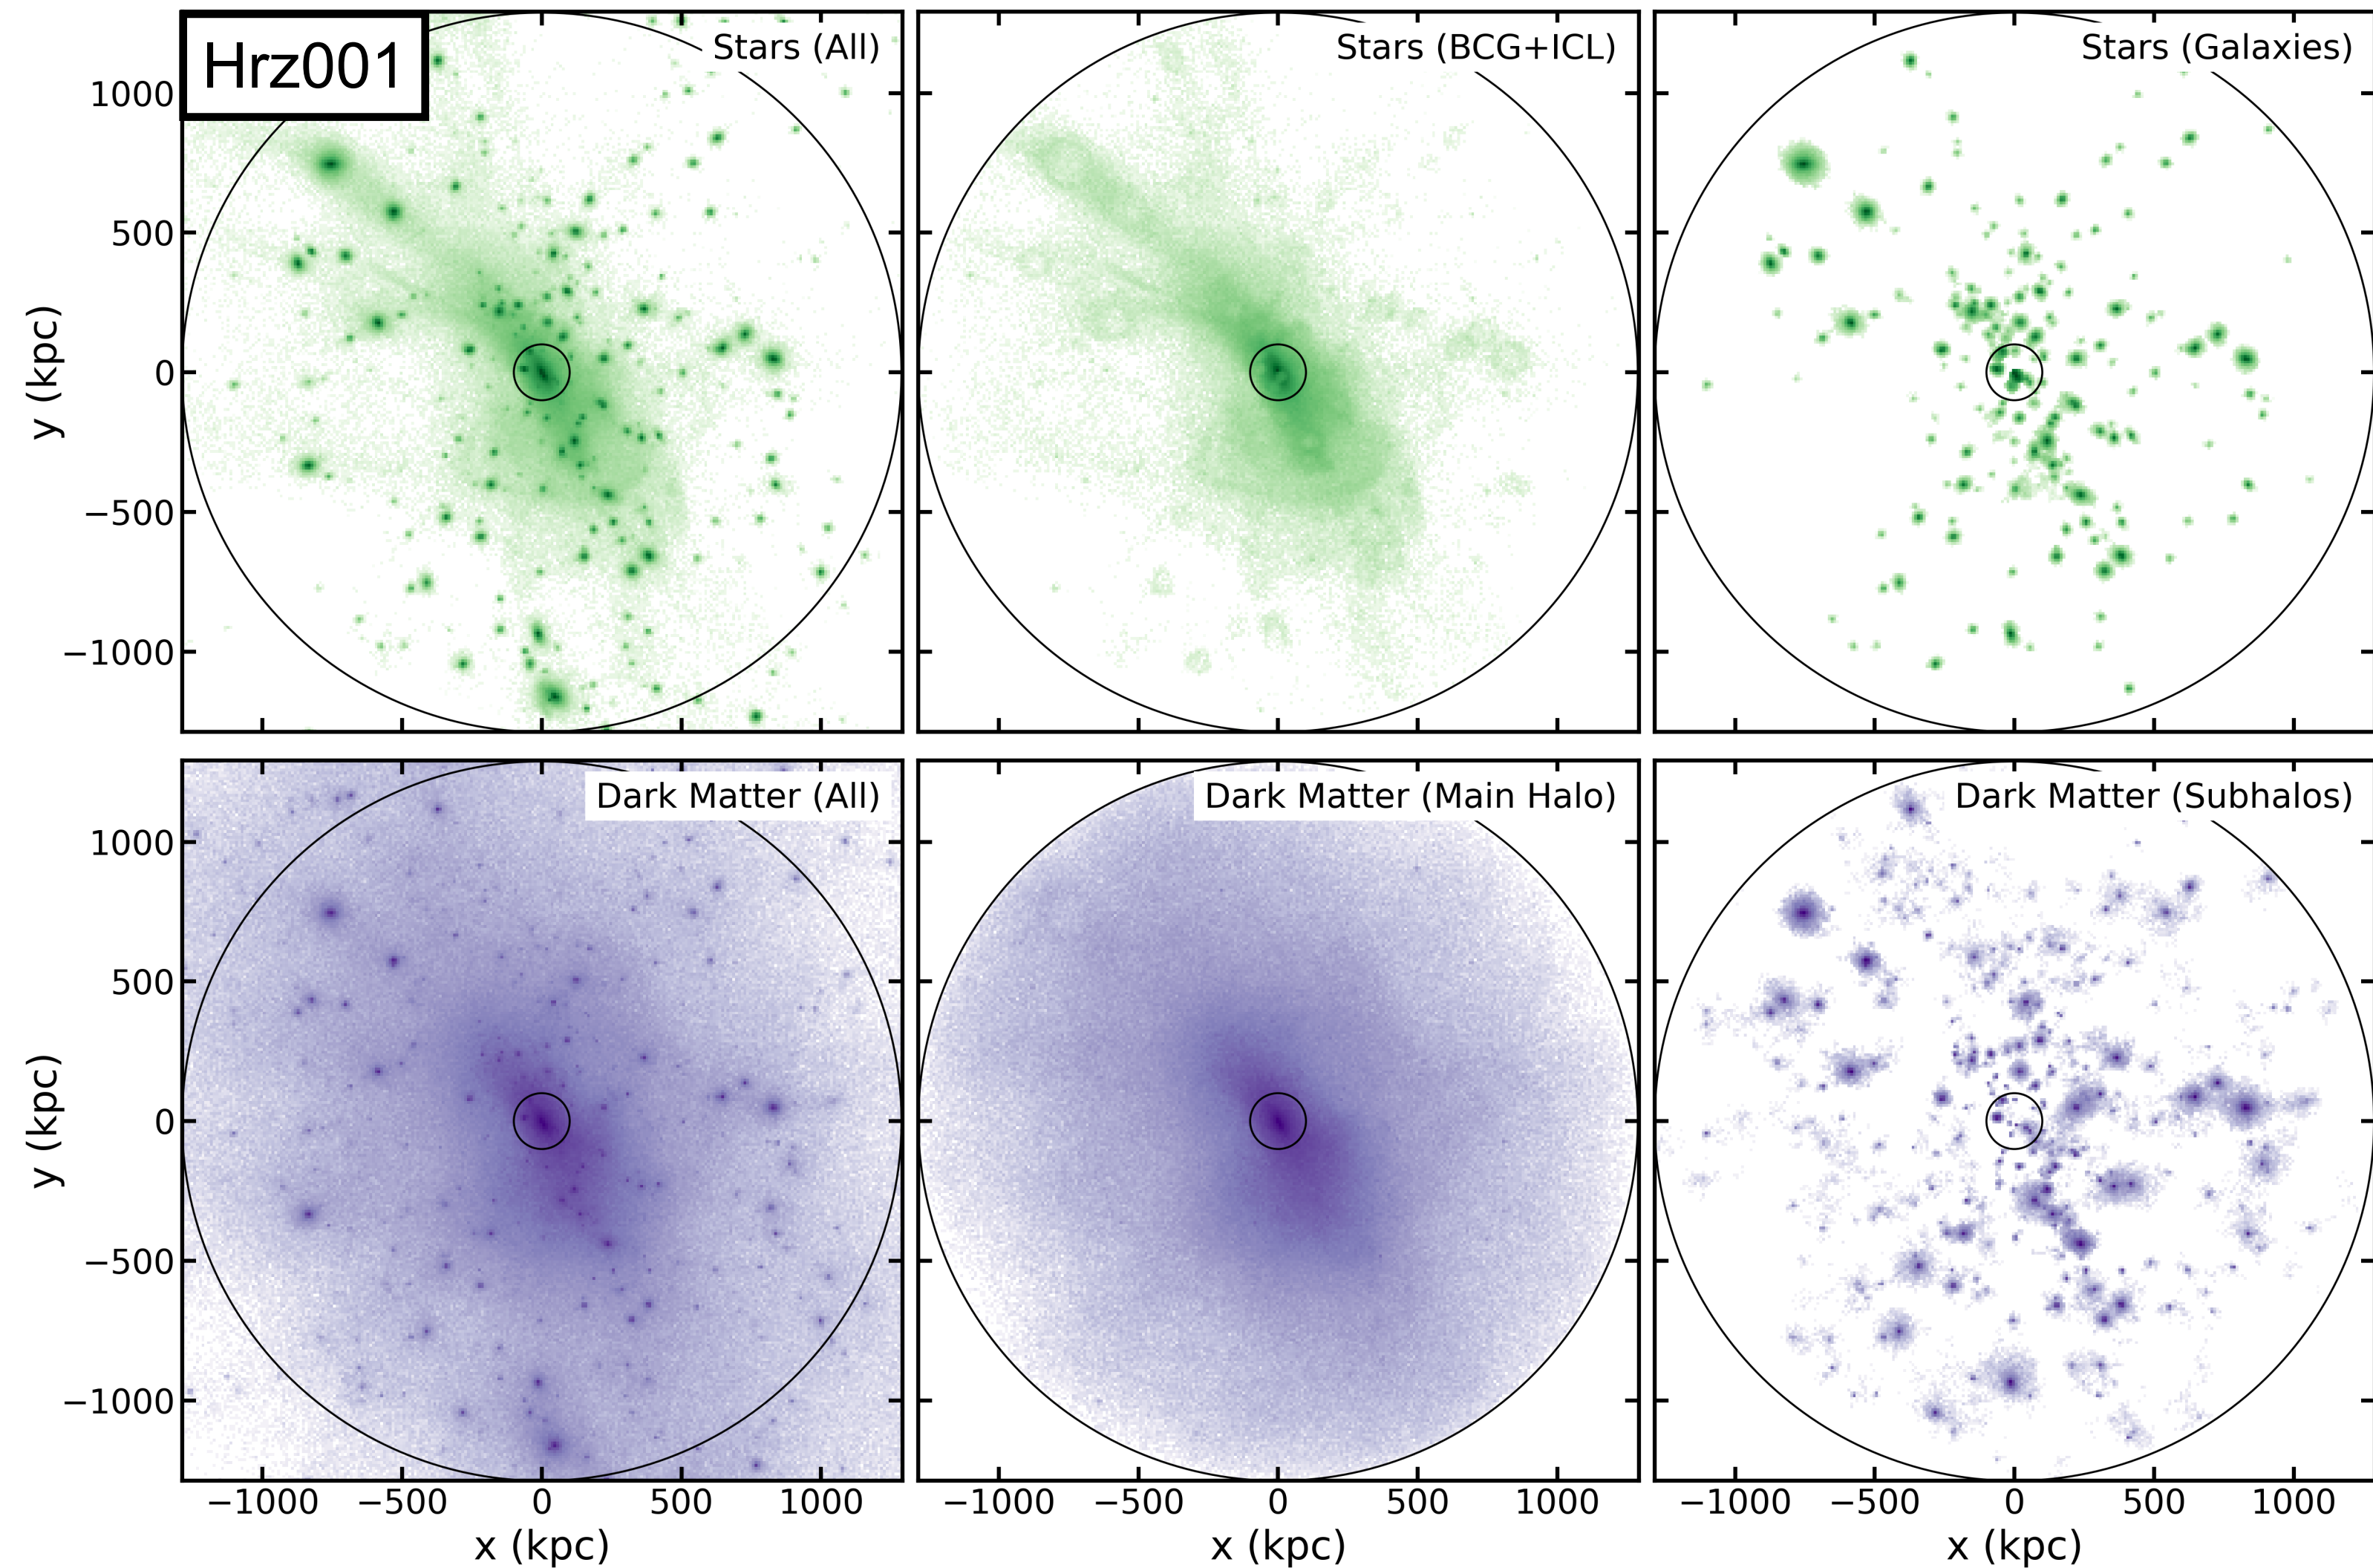

Alonso Asensio+ 2020

Simulation

- 12 clusters from Horizon-AGN, a cosmological hydrodynamic simulation.
- BCG & ICL separation at 100 kpc.

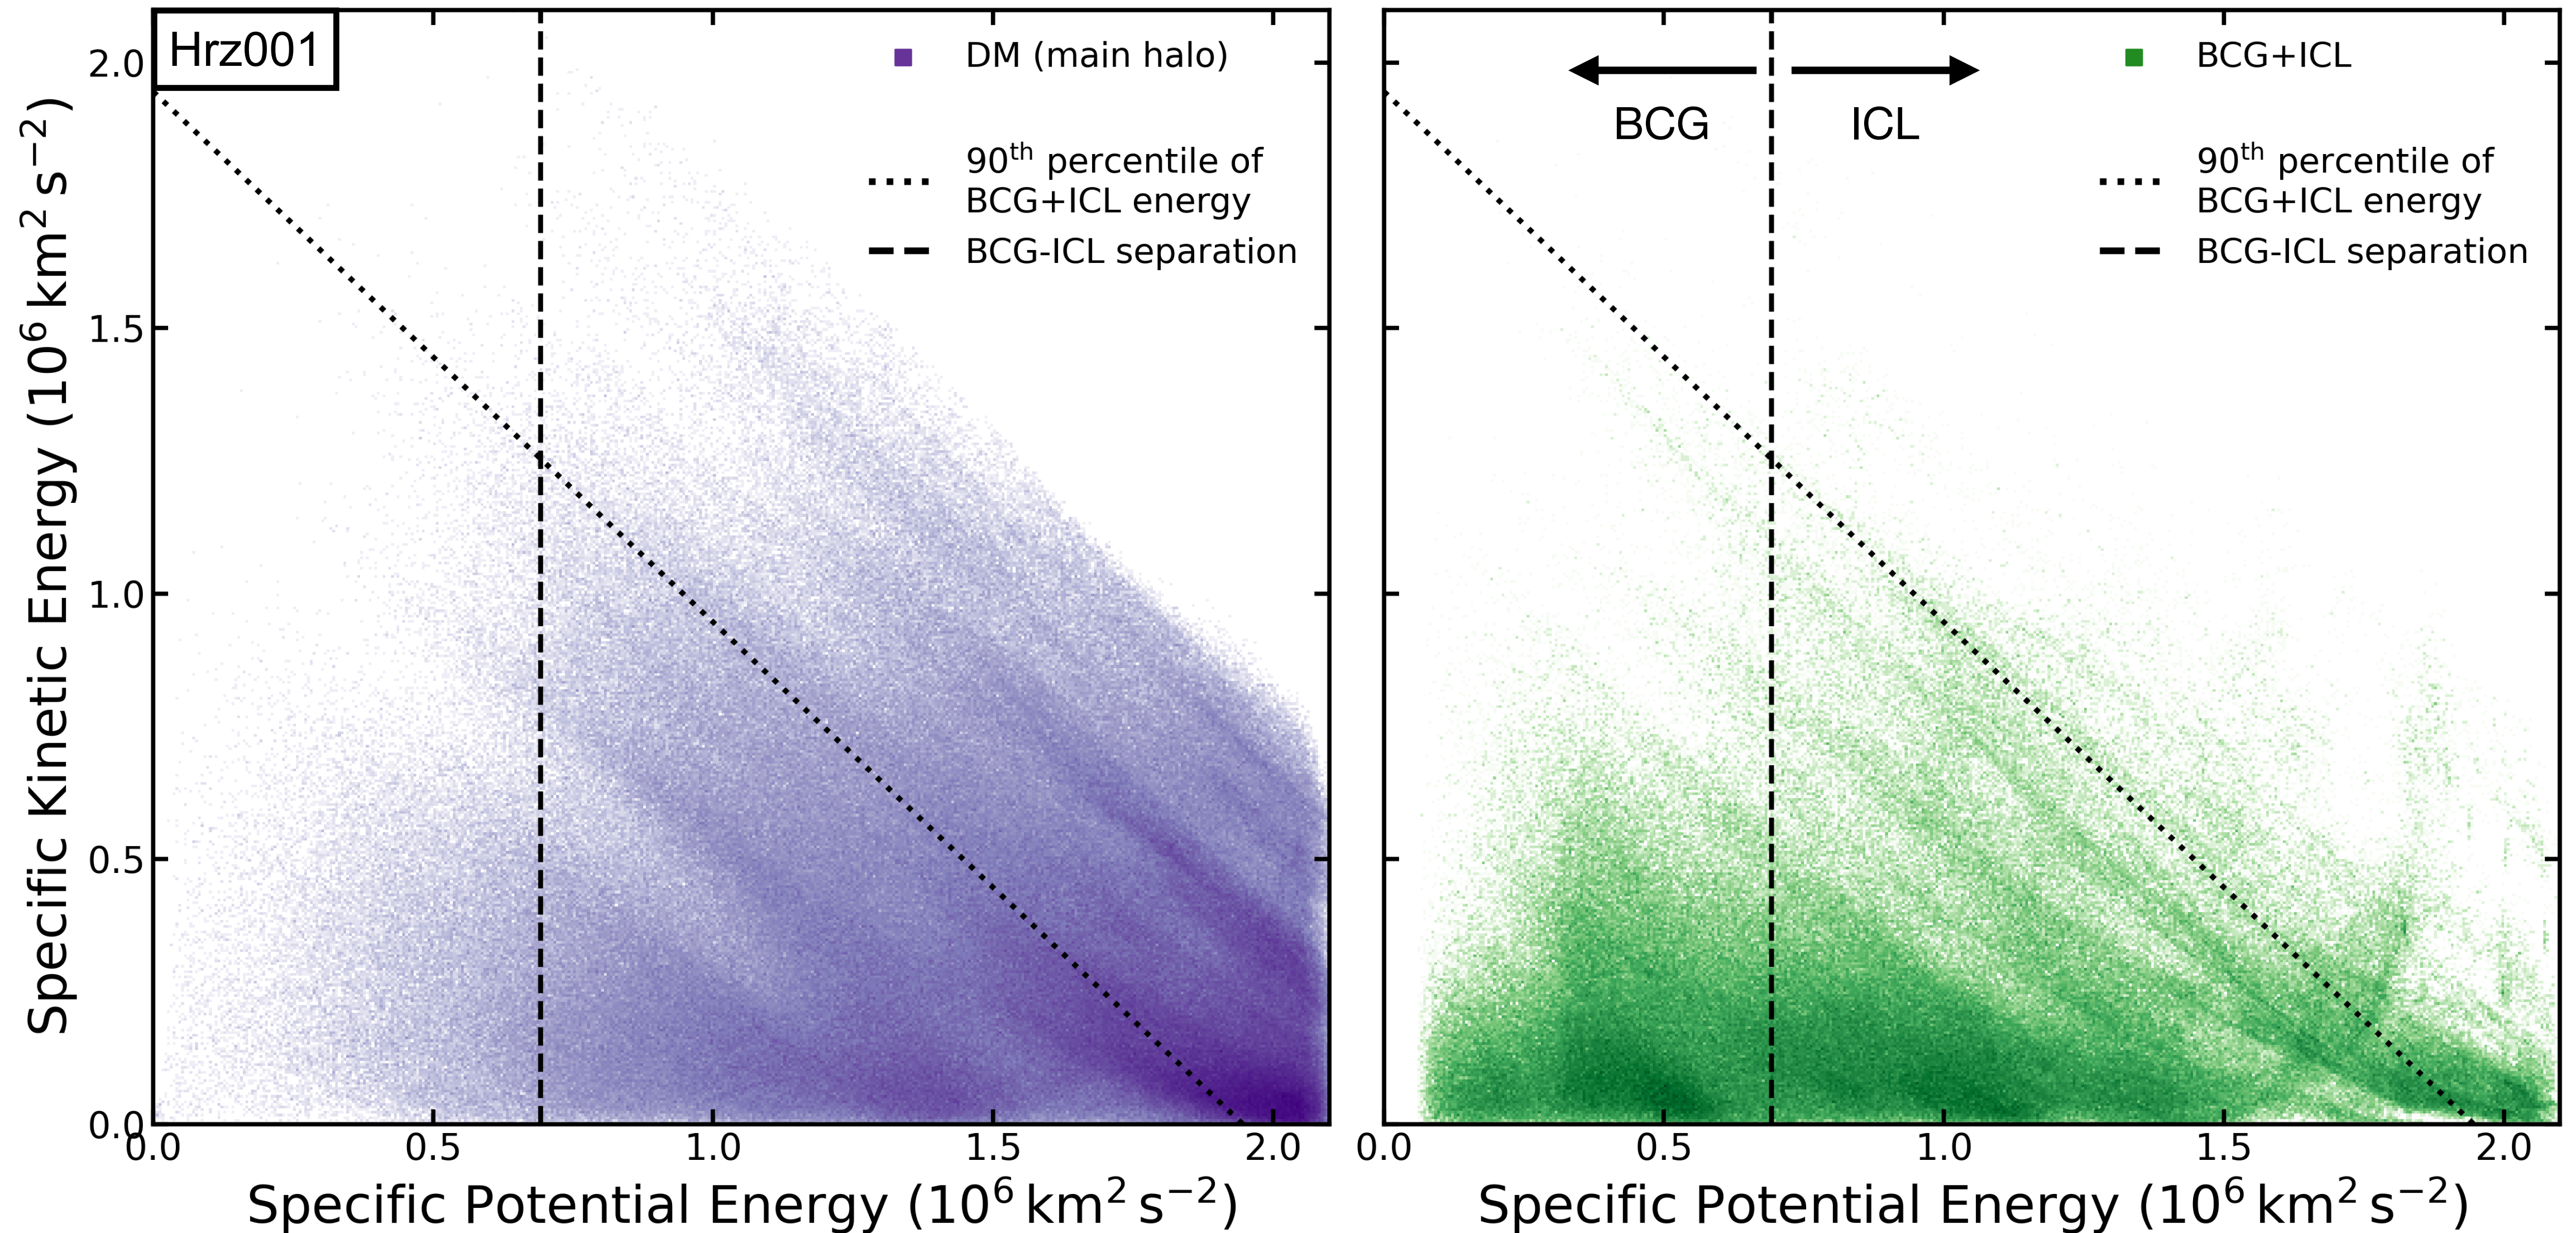

L_{box}	$100 h^{-1} \text{ Mpc}$
$M_{\text{DM,res}}$	$8 \times 10^7 M_{\odot}$
$M_{\text{gas,res}}$	$1 \times 10^7 M_{\odot}$
$M_{\text{star,res}}$	$2 \times 10^6 M_{\odot}$
M_{cluster}	$1 - 4 \times 10^{14} M_{\odot}^{[1]}$

[1] The two most massive clusters in Horizon-AGN are excluded from this study, and thus are not included in this range.

Energetics

$$\text{Specific Energy} = \frac{v^2}{2} + (\phi - \phi_{\min})$$

Energetics

$$\text{Specific Energy} = \frac{v^2}{2} + (\phi - \phi_{\min})$$

Energetics

- Orbital energies of intracluster stars are ~25% lower than the DM and the shapes of the distributions are very different.

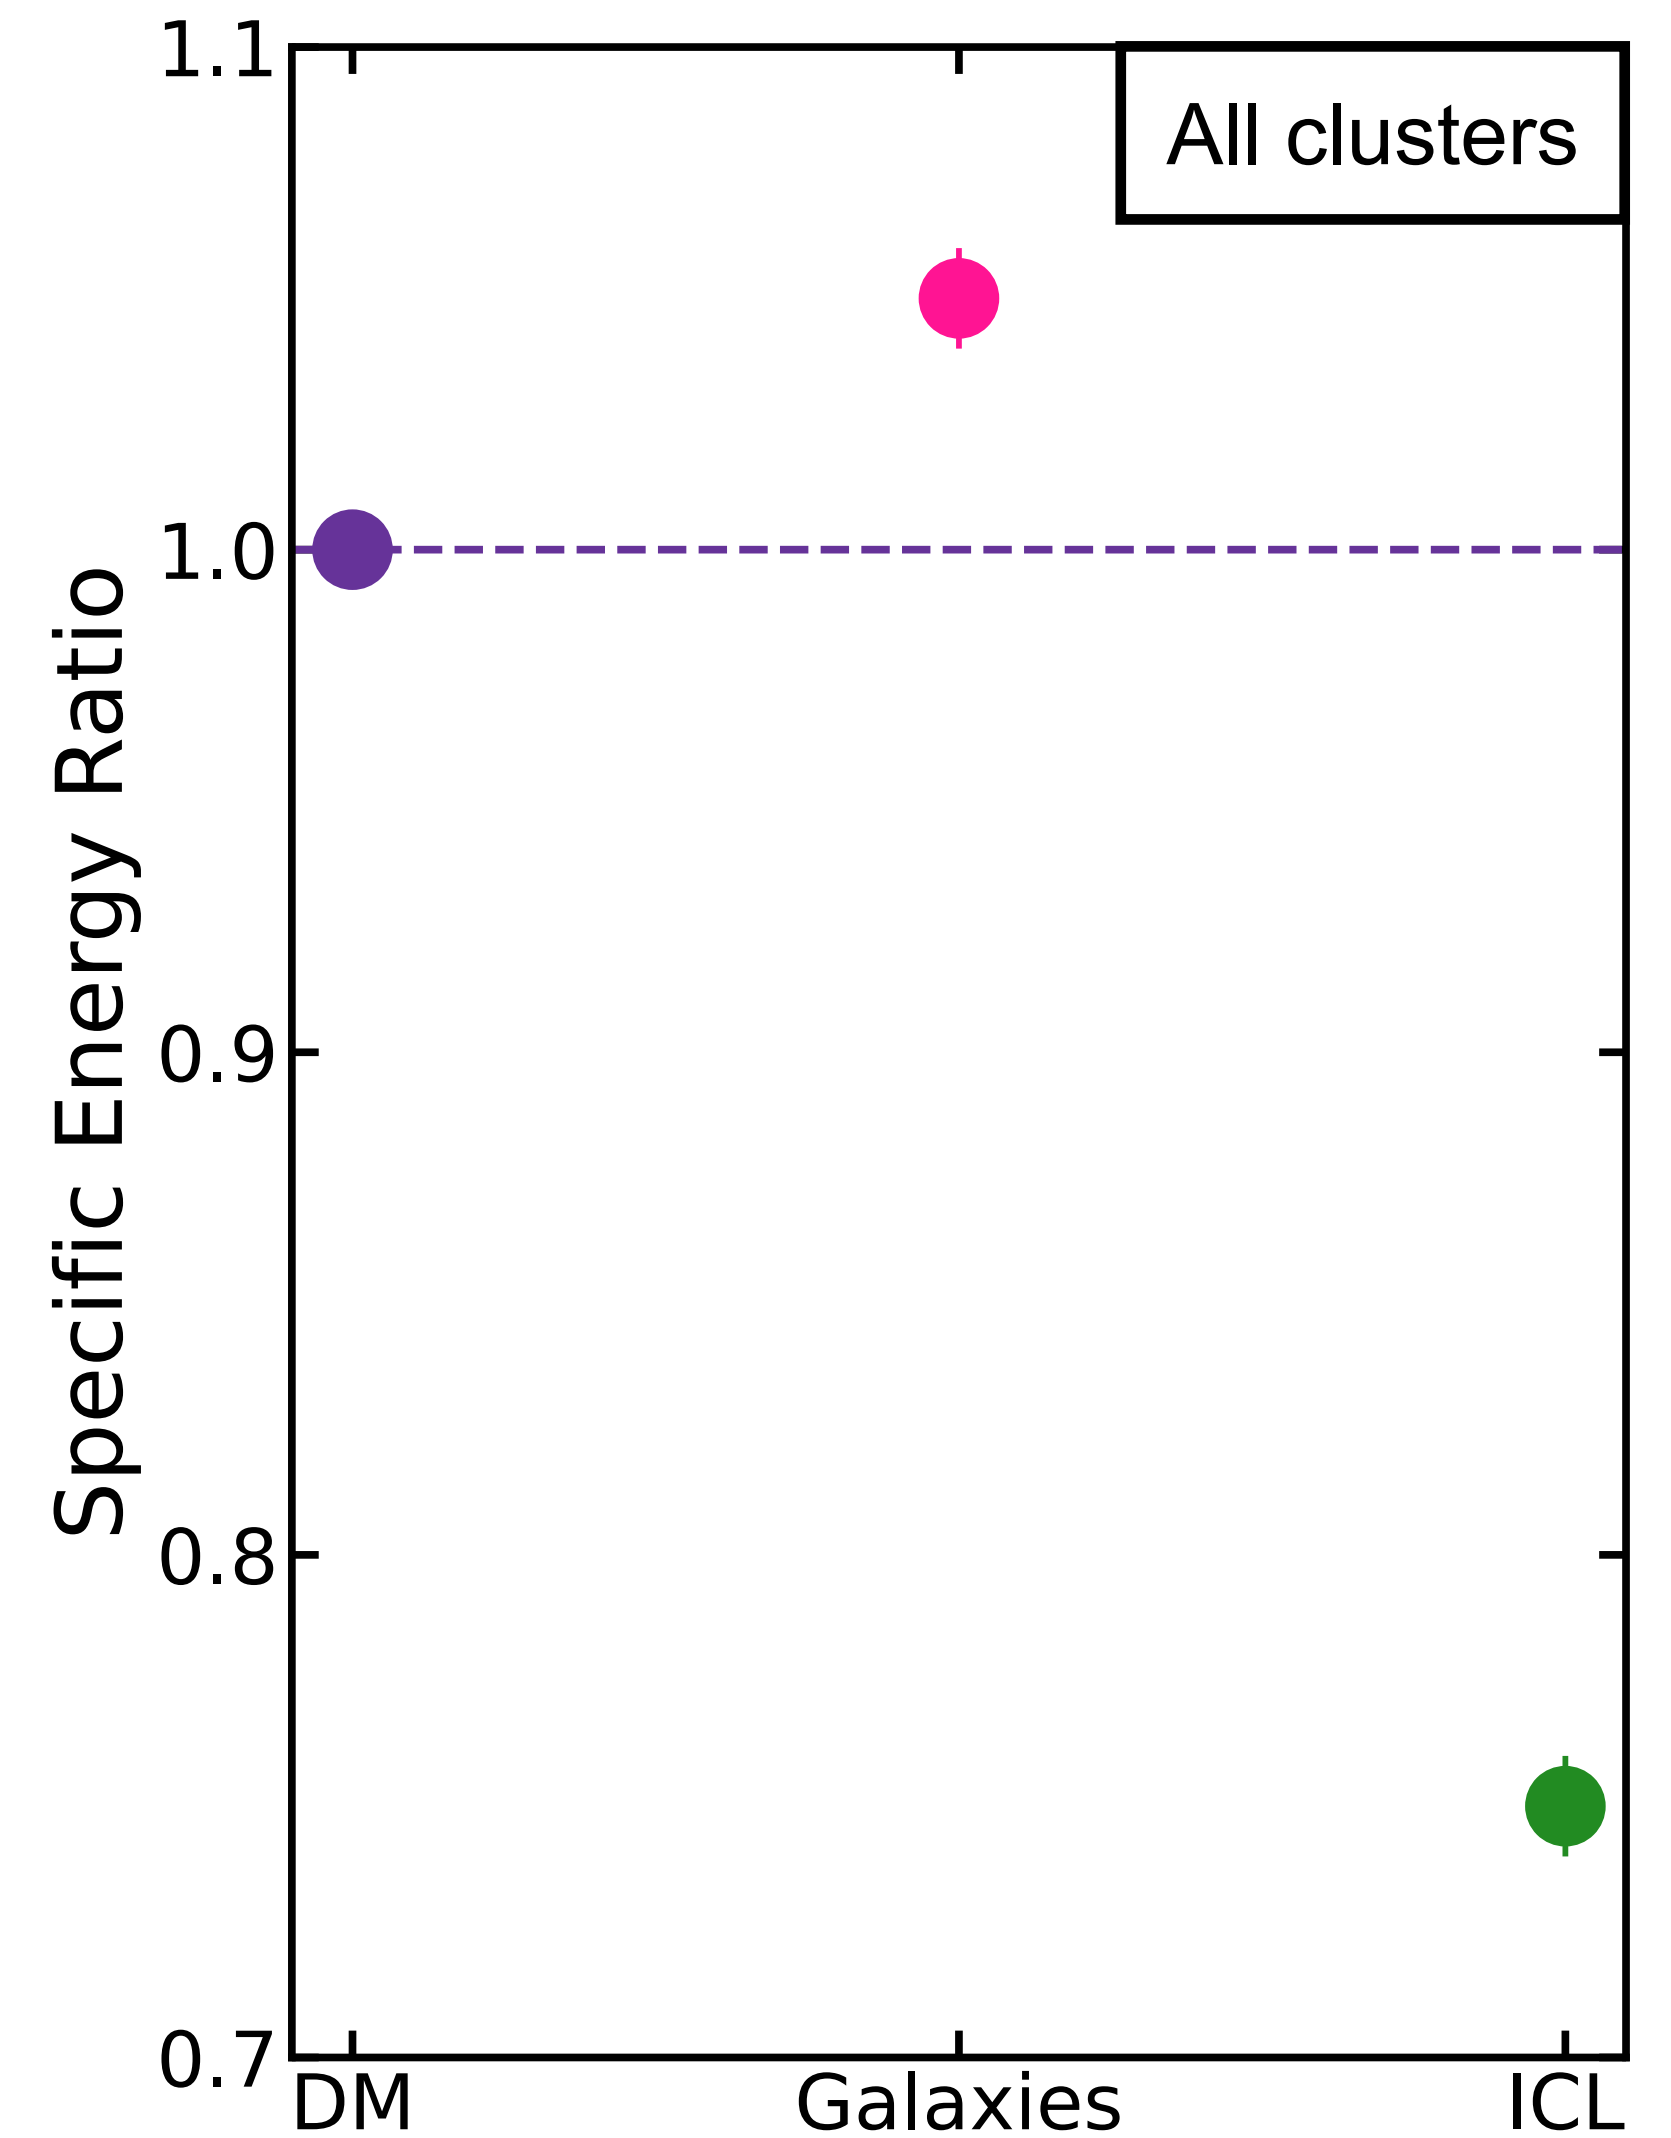

Energetics

- Orbital energies of intracluster stars are ~25% lower than the DM and the shapes of the distributions are very different.

Energetics

- Orbital energies of intracluster stars are ~25% lower than the DM and the shapes of the distributions are very different.

Anisotropy

$$\beta(r) = 1 - \frac{\sigma_{\theta}(r)^2 + \sigma_{\phi}(r)^2}{2 \sigma_r(r)^2}$$

- $\beta = 1$: Radial orbits
- $\beta = 0$: Isotropic orbits
- $\beta \rightarrow -\infty$: Circular orbits
- Galaxy and DM profiles similar.
- ICL more radially biased.

A possible mechanism

- Most tidal stripping occurs at pericentre.

A possible mechanism

- Most tidal stripping occurs at pericentre.
- Tidal stripping more efficient at smaller pericentric distances.

A possible mechanism

- Most tidal stripping occurs at pericentre.
- Tidal stripping more efficient at smaller pericentric distances.
- Pericentric distance minimised for low energy and radial orbits.

A possible mechanism

- Most tidal stripping occurs at pericentre.
- Tidal stripping more efficient at smaller pericentric distances.
- Pericentric distance minimised for low energy and radial orbits.
- Could lead to biases in orbital properties of stripped material.

A possible mechanism

- Most tidal stripping occurs at pericentre.
- Tidal stripping more efficient at smaller pericentric distances.
- Pericentric distance minimised for low energy and radial orbits.
- Could lead to biases in orbital properties of stripped material.
- Stars are more tightly bound than dark matter in subhaloes -> biases less prominent for dark matter.

Why is this important?

- ICL is not an unbiased proxy for the DM distribution.
- Need to understand the processes that produce the intracluster stars and the origin of these differences with the DM.
